Declaration

I undersigned, hereby declare that the project titled “Data-Driven Risk Modelling for Tapioca Yield Prediction” submitted in partial fulfilment of the requirements for the award of degree of Master of Technology of the APJ Abdul Kalam Technological University, Kerala is a bonafide work done by me under the supervision of Prof. Ramu Rajendran. This submission represents my ideas in my own words and where ideas or words of others have been included, I have adequately and accurately cited and referenced the original sources. I also declare that I have adhered to ethics of academic honesty and integrity and have not misrepresented or fabricated any data or idea or fact or source in my submission. I understand that any violation of the above will be a cause for disciplinary action by the institute and/or the University and can also evoke penal action from the sources which have thus not been properly cited or from whom proper permission has not been obtained. This report has not been previously formed the basis for the award of any degree, diploma, or similar title of any other university.

ABSTRACT

Agricultural yield variability presents significant challenges for production planning, supply-chain stability, and financial risk management, particularly for climate-sensitive crops such as tapioca. Traditional yield estimation methods often attempt direct prediction using historical yield records, despite limited data availability and the influence of multiple non-climatic factors. This project proposes a yield-risk forecasting framework that emphasizes the identification and quantification of environmental stress exposure rather than precise yield prediction. The approach characterizes stress conditions by evaluating weather patterns, soil conditions, and localized environmental signals to identify periods of moisture deficit, thermal stress, and their combined effects. Annual stress exposure is represented as the proportion of time during which adverse conditions occur, enabling an interpretable and scalable assessment of crop stress. A baseline yield serves as a reference for expected production under normal conditions and is adjusted using a conservative penalty mechanism based on the severity of observed stress. The framework is designed to support the integration of local soil information to enhance the spatial and temporal resolution of stress detection. By prioritizing transparency, robustness, and adaptability, the proposed methodology aims to provide a practical tool for yield-risk assessment in tapioca cultivation, with potential applications in off take planning, supply-chain risk management, and agricultural financing.

Chapter 1

INTRODUCTION

Agriculture in Kerala is a high-stakes, multi-modal sector where traditional staples like Tapioca (*Manihot esculenta*) play a dual role as a critical industrial resource for the starch and sago industries and as a primary culinary staple for regional food security. Despite its economic importance, the sector remains highly vulnerable to climate-induced variability, with the current supply chain management and agricultural financing hindered by a significant reporting lag in official government yield statistics. This information gap creates a critical blind spot for financial institutions, who are forced to extend credit through schemes like the Kisan Credit Card based on yield data that is typically 24 to 36 months out of date. Consequently, if a localized climate disaster or pest outbreak occurs, the official data confirming the crash may not be available until long after loans have entered default, leading to an accumulation of Non-Performing Assets (NPAs). This project addresses the urgent need for a real-time, data-driven yield risk modelling framework that provides financial stakeholders with a 90-day lead time before the May harvest, enabling proactive loan default mitigation and logistical optimization. The motivation for this study is rooted in the complex physiological "Crop Clock" of Tapioca in Kerala, which follows a 12-month cycle beginning with planting during the Southwest Monsoon in June. Because the plant remains in the ground for a full year, it is exposed to a volatile spectrum of climatic stressors, ranging from monsoon waterlogging to pre-harvest heatwaves. Traditional yield models often rely on simple annual weather averages, which fail to capture the non-linear, stage-dependent sensitivity of the crop. Biologically, the first five months of growth—encompassing establishment and tuber initiation—are the most critical, accounting for an estimated 60% of the final yield determination. Stress during this window causes irreversible stunting that cannot be corrected by later rains. Furthermore, Tapioca suffers from a unique logistical constraint known as Post-harvest Physiological Deterioration (PPD), where the tubers begin to rot within 48 to 72 hours of harvest. This perishability makes high-

precision, pre-harvest forecasting essential for supply chain managers who must coordinate labor and transport to minimize post-harvest losses that currently range between 15% and 40% in the region. To solve these challenges, this project develops a multi-modal risk engine that fuses 16 years of daily climatic data from NASA's POWER API with high-precision multispectral imagery from the Sentinel-2 satellite mission. A significant technical hurdle in Kerala is the prevalence of intercropping, where Tapioca is grown beneath the permanent canopies of Coconut and Rubber trees. This "Green Haze" creates significant spectral noise that blinds standard satellite indices like NDVI. To overcome this, the framework implements the Weighted Difference Vegetation Index (WDVI) and utilizes a 100-meter spatial buffer anchored to government-validated tube well coordinates. This approach ensures that the biological "Ground-Truth" is isolated from residential or perennial tree noise. By optimizing the model's sensitivity to a validated constant of 0.10, the system mathematically confirms the crop's inherent hardiness while providing a conservative "Lendable Yield" floor. The final output is an operational SaaS prototype that translates complex plant biology and space-based data into actionable financial metrics, such as the Productivity-to-Debt (PtD) ratio, providing a scientifically grounded decision-support tool for the future of agricultural financing in India.

Chapter 2

LITERATURE REVIEW

2.1 Overview

Recent advancements in remote sensing, geospatial analytics, and machine learning have significantly improved agricultural monitoring, crop suitability analysis, drought assessment, and yield prediction. Satellite platforms such as Sentinel-2, Landsat, and MODIS have enabled researchers to extract vegetation, moisture, and land surface indicators useful for understanding crop health and productivity.

Many recent studies have also combined remote sensing data with machine learning algorithms and decision-support frameworks to support crop management, drought monitoring, and land suitability assessment. These approaches are especially useful for tropical and drought-prone crops such as tapioca, cassava and sugarcane, where climate variability and soil conditions strongly affect productivity. The following studies provide an important foundation for the present work by demonstrating how remotely sensed data can be applied for crop growth monitoring, stress detection, land suitability analysis, and yield estimation.

2.1.1 The Quest for High Yielding Drought-Tolerant Cassava Variety[1]

This study investigates the morpho-physiological performance of cassava varieties under well-watered and water-deficit conditions to identify traits associated with drought tolerance and high yield. The authors found that water stress significantly reduced plant height, leaf area index, leaf retention, and photosynthetic performance. However, varieties that maintained higher photosynthetic activity, better leaf retention, and stronger harvest index produced better yields under stress conditions.

2.1.2 Using Sentinel-2 Images for Tropical Economic Crops Growth Modeling[2]

This study investigates the use of Sentinel-2 multispectral imagery for modelling the growth of tropical economic crops. The paper emphasizes the ability of Sentinel-2 data to capture crop growth variations through spectral reflectance patterns and vegetation-related indicators. By analyzing temporal satellite observations, the study demonstrates how crop growth status can be monitored efficiently over large agricultural regions.

2.1.3 A Possible Role of Copernicus Sentinel-2 Data to Support Common Agricultural Policy Controls in Agriculture[3]

This paper examines the role of Copernicus Sentinel-2 data in supporting agricultural monitoring and policy-based control activities. The study shows that Sentinel-2 imagery can be used for identifying crop conditions, monitoring land use, and improving agricultural verification processes. The authors suggest that satellite-based monitoring can reduce dependence on traditional field inspections and improve large-scale agricultural supervision.

2.1.4 Land Suitability Assessments for Yield Prediction of Cassava Using Geospatial Fuzzy Expert Systems and Remote Sensing[4]

This study proposes a geospatial fuzzy expert system for cassava land suitability assessment and yield prediction. The authors integrate remote sensing-based vegetation variables such as NDVI, SAVI, IRECI, LAI, and fAPAR to estimate cassava productivity across different land suitability classes. The study demonstrates that combining land suitability analysis with satellite-derived vegetation indicators improves the reliability of yield prediction.

2.2 Research Gaps

- Most existing studies focus on crop yield estimation or land suitability, but do not explicitly model yield risk under adverse climate conditions.
- Very few studies specifically address tapioca/cassava yield prediction in Kerala

using a block-level, long-term, data-driven framework integrating climate and satellite indicators.

- Most remote sensing-based agricultural studies emphasize vegetation condition monitoring, but fail to link these indicators directly to yield loss and financial/agronomic risk.
- Existing yield prediction approaches generally rely on average climatic variables, which are inadequate for capturing extreme and compound stress conditions such as simultaneous heat and moisture stress.
- Current cassava-related studies rarely incorporate crop physiological growth-stage sensitivity, resulting in models that do not reflect the differential impact of stress across crop development phases.
- There is limited work integrating historical yield baselines, Sentinel-2 vegetation indices, and climate-derived stress penalties into a unified, interpretable risk-adjusted yield modelling framework.
- Most prior studies are designed for agronomic or academic analysis only, with limited translation into real-time decision-support tools for stakeholders such as farmers, planners, supply-chain actors, or agricultural lenders

2.3 Motivation

- To address the uncertainty in tapioca yield caused by changing climatic and environmental conditions.
- To move beyond traditional yield estimation methods and develop a more reliable data-driven risk assessment framework.
- To identify how heat stress, moisture stress, and compound climatic stress affect tapioca productivity at the block level.
- To support better planning and decision-making for farmers, policymakers, and agricultural stakeholders through interpretable yield risk insights.
- To utilize satellite data and historical climate information for timely and scalable agricultural monitoring in Kerala.

Chapter 3

PROBLEM DEFINITION

3.0.1 Problem Statement

Agricultural yield, particularly for climate-sensitive crops such as tapioca, is highly influenced by environmental variability including rainfall, temperature, and soil conditions. In Kerala, the problem is further aggravated by delays in the availability of official yield statistics, creating a significant information gap for stakeholders. Existing yield prediction methods rely on historical data and direct forecasting, which often fail to capture real-time environmental stress and its cumulative impact on crop productivity. This limits effective decision-making in production planning, supply-chain management, and agricultural financing. Hence, there is a need for a reliable and interpretable framework that focuses on assessing yield risk through environmental stress analysis, enabling timely and informed decisions.

3.0.2 Objectives

This project aims to develop a multi-modal, data-driven yield-risk modelling framework for tapioca cultivation by integrating climatic and satellite data with agronomic principles. The framework focuses on identifying environmental stress, modelling its impact on crop productivity, and linking biological outcomes with financial risk indicators to support informed decision-making.

The objectives of this project work are:

1. To integrate climate, satellite, and historical agricultural data into a unified risk model.
2. To develop a stress-based agronomic model using adaptive thresholds and growth-stage (60/30/10) weighting.

3. To address spectral interference in satellite analysis using indices such as WDVl and localized sampling techniques.
4. To link yield–risk outcomes with financial indicators such as the Productivity–to–Debt (PtD) ratio for risk assessment.

3.0.3 Scope of Project Work

This project focuses on developing a data-driven framework for assessing yield risk in tapioca cultivation by analyzing environmental stress factors and their impact on crop productivity. The scope of the work is limited to the integration of climate data, satellite-derived indices, and historical agricultural data to model stress exposure and its influence on yield variability. The methodology is designed to evaluate crop stress using physiological and growth-stage-based weighting mechanisms, enabling an interpretable estimation of yield risk. The results are based on the proposed model and its parameter settings, including stress penalties and baseline yield assumptions, and are valid within the context of the selected dataset and study region. The conceptual design emphasizes robustness and scalability, but does not aim to provide exact yield prediction. Instead, it offers a risk-oriented perspective that supports decision-making. The applicability of the model extends to agricultural planning, supply-chain optimization, and financial risk assessment, particularly in scenarios where timely yield data is unavailable. However, the framework is constrained by data availability, model assumptions, and regional conditions, and may require further calibration for use in different crops or geographical locations.

3.0.4 Research Methodology

This project adopts a data-driven approach to develop a yield-risk modelling framework for tapioca cultivation by integrating climatic, satellite, and historical agricultural data. The problem was identified based on the need to assess crop performance under varying environmental conditions using a risk-oriented perspective rather than direct yield prediction. The methodology involves the collection and integration of multi-source data, including long-term climate datasets and satellite-derived vegetation indices. Data preprocessing techniques are applied to ensure temporal and spatial alignment, followed by analysis to identify key stress conditions such as heat and moisture stress. A modelling framework is then developed by incorporating agronomic principles, including growth-stage-based weighting and stress thresholds, to evaluate the cumulative impact of environmental factors on crop productivity. Techniques are also

implemented to address region-specific challenges such as spectral interference due to intercropping. The model outputs are analyzed and validated against historical trends to assess performance and reliability. Finally, the results are interpreted to generate actionable insights for agricultural planning, supply-chain optimization, and financial risk assessment.

3.0.5 Limitations of the Project Work

The proposed yield-risk modelling framework is subject to certain limitations related to data quality, model assumptions, and methodological constraints. The accuracy of the results depends on the reliability and resolution of climate data and satellite imagery used in the study. Any missing values, temporal gaps, or spatial mismatches during data integration may affect the precision of stress detection and yield-risk estimation. Additionally, the model relies on predefined parameters such as growth-stage weightings, stress thresholds, and baseline assumptions, which may not fully capture the complex and dynamic biological responses of tapioca under varying environmental conditions. Furthermore, the framework primarily focuses on environmental stress factors and does not explicitly incorporate other influences such as pest infestations, disease outbreaks, or variations in farm management practices. The model has been developed for a specific regional context and crop type, and its direct applicability to other regions or crops may require recalibration and further validation. Practical challenges encountered during the project, including data preprocessing, handling spectral interference, and integrating multi-source datasets, also impose limitations on the overall system performance.

Chapter 4

METHODOLOGY

4.1 Overview

This chapter presents the step-by-step methodology used to build the proposed yield-risk modelling framework. The workflow begins with data collection and preprocessing, followed by spatio-temporal alignment, physiological stress modelling, spectral vitality assessment, yield-risk estimation, and financial interpretation.

4.2 Data Collection

Data collection is the first methodological step in this study. Multi-source datasets were assembled from climate repositories, satellite imagery products, and historical agricultural records. Specifically, long-term climate variables were obtained from NASA POWER, vegetation-related indicators were derived from Sentinel-2 observations, and baseline yield information was compiled from PMFBY and associated government records. Preliminary expert inputs from CTCRI were also used to support parameter selection and contextual interpretation. The collected datasets were then cleaned and temporally aligned to prepare consistent inputs for the subsequent modelling stages.

4.3 Spatio-Temporal Framework

The proposed model is built upon a structured spatio-temporal framework designed to accurately represent the growth cycle and environmental conditions of tapioca cultivation in Kerala. This framework ensures that both time-based and location-specific factors influencing crop performance are effectively captured.

4.3.1 Temporal Framework (Crop Clock Logic)

The model operates on a 12-month "Crop Clock" tailored to the tapioca cultivation cycle in Kerala, which extends from June (planting phase) to May (harvest phase). Since the crop spans across two calendar years, a "year-wrap" logic is implemented to maintain temporal consistency. Accordingly, climatic and satellite data from January to May are mapped to the crop cycle that began in June of the previous year. This approach ensures that all environmental inputs are correctly aligned with the biological growth stages of the crop, enabling accurate assessment of stress conditions throughout the lifecycle.

4.3.2 Spatial Framework (Farm-Cluster Anchoring)

To improve spatial accuracy and reduce noise in satellite observations, the model adopts a location-specific anchoring strategy. Instead of relying on general geometric centroids, which may include non-agricultural areas, the framework utilizes validated tube well coordinates as proxies for active agricultural zones. Around each coordinate, a 100-meter "farm-cluster" buffer is defined to capture localized crop conditions. This spatial approach helps to minimize spectral interference caused by surrounding features such as residential areas or perennial tree canopies, thereby improving the reliability of satellite-derived indicators. By combining precise spatial anchoring with temporal alignment, the framework establishes a strong foundation for subsequent stress analysis and yield-risk modelling.

4.4 Physiological Stress Modelling

The physiological stress modelling component is designed to quantify the impact of environmental stressors on tapioca crop performance using climate data. Unlike conventional approaches that rely on fixed threshold values, this model adopts an adaptive, data-driven methodology to capture location-specific stress conditions.

4.4.1 Adaptive Localized Thresholds (Percentile-Based Approach)

To account for regional climatic variability, the model utilizes adaptive thresholds derived from long-term historical data. For each spatial coordinate, approximately 16 years of climatic data is analyzed to establish percentile-based benchmarks for identifying extreme conditions.

Heat Stress Threshold (P90 – T₉₀): This represents the temperature level that is exceeded only 10% of the time. Values above this threshold indicate extreme heat stress conditions.

Moisture Stress Threshold (P10 – M₁₀): This represents the lower bound of soil moisture, below which conditions occur only 10% of the time. Values below this threshold indicate severe moisture deficit.

This percentile-based approach ensures that stress detection is localized and adaptive, rather than relying on generalized or fixed thresholds that may not accurately reflect regional conditions.

4.4.2 Compound Stress and Stage-Based Weighting

Crop response to environmental stress is not uniform throughout its growth cycle. To capture this biological behavior, the model incorporates both compound stress effects and growth-stage-based weighting.

The cumulative impact of daily stress conditions is quantified using a **Weighted Stress Index (WSI)**, defined in Eq. (4.1):

$$WSI = \sum (Stress_{daily} \times Weight_{stage}) \quad (4.1)$$

Where:

- $Stress_{daily} = 1.0$ for a single stress condition (either heat or moisture)
- $Stress_{daily} = 1.5$ when both heat and moisture stress occur simultaneously (compound synergy penalty)
- $Weight_{stage}$ represents the relative importance of each growth stage.

Growth Stage Weighting (60/30/10 Rule)

The model assigns differential weights to various stages of crop growth based on physiological sensitivity:

- Stage 1 (Months 1–5: Establishment & Tuber Initiation) – 60% weight

- Stage 2 (Months 6–10: Bulking Phase) – 30% weight
- Stage 3 (Months 11–12: Maturity Phase) – 10% weight

This weighting mechanism reflects the biological reality that early-stage stress has a more significant and often irreversible impact on final yield.

4.5 Multi-Modal Spectral Fusion (Sentinel-2)

To accurately assess crop health in Kerala’s complex intercropping environment, this study implements a multi-modal spectral fusion approach using Sentinel-2 satellite imagery, consistent with prior Sentinel-2 based agricultural monitoring studies [12, 14, 16]. The presence of permanent coconut and rubber canopies creates significant spectral interference, often masking the actual condition of understory crops like tapioca. To address this challenge, a Triple-Index Vitality framework is developed to isolate and quantify true crop health.

4.5.1 WDVl-Based Intercrop Filtering

Conventional vegetation indices such as NDVI are often insufficient in intercropped regions due to canopy dominance. To overcome this limitation, the model employs the Weighted Difference Vegetation Index (WDVI), which is specifically effective in separating vegetation signals from soil and background noise.

The WDVl is calculated as shown in Eq. (4.2):

$$WDVI = NIR - (\gamma \times Red) \quad (4.2)$$

Where:

- *NIR* represents near-infrared reflectance,
- *Red* represents red band reflectance,
- γ is the soil-line slope, taken as 1.5 for Kerala’s laterite soils.

This formulation helps isolate the spectral signature of tapioca beneath overstory vegetation, thereby improving the accuracy of crop health assessment in intercropped conditions.

4.5.2 Triple-Index Vitality Score

To enhance robustness, the model integrates multiple vegetation indices into a unified metric called the Vitality Score. This score combines:

- NDVI (40%) – representing overall vegetation greenness,
- NDWI (30%) – indicating moisture content,
- WDVI (30%) – capturing understory vegetation health.

By combining these indices, the model reduces dependence on any single metric and provides a more comprehensive representation of crop condition, aligning with multi-sensor and multi-index yield modelling evidence [2, 19].

4.5.3 Vitality Multiplier

The relative health of the crop is quantified using a Vitality Multiplier (V), defined as the ratio of the current vegetation score to its historical average in Eq. (4.3):

$$V = \frac{Score_{current}}{Score_{mean}} \quad (4.3)$$

This normalization allows the model to detect deviations from typical crop conditions, enabling early identification of stress or decline in productivity.

4.6 Yield Forecasting Model

The final stage of the methodology involves the development of a yield forecasting model that integrates climatic stress, biological crop health, and management history into a unified framework. This model is designed to provide a risk-adjusted estimate of yield by combining multiple components derived from previous stages of analysis.

4.6.1 Model Formulation

The final yield forecast(Y_f) is computed using Eq. (4.4):

$$Y_f = \text{Baseline} \times [1 - (WSI \times S)] \times V^2 \times Shock_{adj} \quad (4.4)$$

This formulation captures the combined effects of environmental stress, crop vitality, and external disruptions on yield.

4.6.2 Model Component

Baseline Yield (Baseline)

The baseline yield represents the expected productivity under normal conditions. In this model, it is estimated using a persistence-based approach (Method A), which assumes that the previous year's yield serves as a reliable reference for the current cycle. This provides a stable starting point for further adjustments.

Stress Impact Factor ($WSI \times S$)

The Weighted Stress Index (WSI), derived from physiological stress modelling, is scaled using a sensitivity parameter S . This parameter is optimized through tuning and is set to 0.10 for the general model, with slight variations based on regional crop characteristics.

This component reduces the baseline yield proportionally to the severity of environmental stress experienced during the crop cycle.

Vitality Adjustment(V^2)

The vitality multiplier V , obtained from spectral analysis, is squared to reflect the non-linear relationship between crop health and yield. This captures the biological phenomenon where small declines in vegetation health can lead to disproportionately large reductions in yield, particularly in starch accumulation.

Shock Adjustment Factor($Shock_{adj}$)

To account for external disruptions, categorical adjustment factors are incorporated. These include events such as extreme climatic conditions or systemic disruptions,

which may impact productivity beyond normal stress conditions. These factors act as multiplicative corrections to the final yield estimate.

4.6.3 Model Interpretation

The proposed model integrates environmental, biological, and external factors into a single interpretable framework. By progressively adjusting the baseline yield using stress penalties, vitality corrections, and shock factors, the model provides a realistic and conservative estimate of crop productivity. This approach ensures that both gradual stress accumulation and sudden disruptions are effectively captured.

4.7 Financial Risk and Price Sensitivity Analysis

In the final stage of the methodology, the estimated yield is translated into financial risk indicators to evaluate the economic viability of tapioca cultivation. This step bridges the gap between agronomic modelling and financial decision-making by converting biological outputs into actionable metrics for lenders and stakeholders.

The yield output(Y_f) is mapped to financial parameters using standardized agricultural financing benchmarks, enabling the assessment of loan repayment capacity and price sensitivity under varying conditions.

4.7.1 Productivity-to-Debt (PtD) Ratio

The Productivity-to-Debt (PtD) ratio is used as a key metric to evaluate the farmer's ability to service agricultural loans. It relates the expected revenue from crop yield to the loan amount, as expressed in Eq. (4.5).

$$PtD = \frac{Y_f \times Price_{market}}{Loan_{amount}} \quad (4.5)$$

Where:

- Y_f is the predicted yield
- $Price_{price}$ is the prevailing market price of tapioca

- $Loan_{amount}$ represents the credit extended to the farmer.

A higher PtD value indicates stronger repayment capacity and lower financial risk, while a lower value signals potential vulnerability to loan default.

4.7.2 Breakeven Price Analysis

To address the impact of market price fluctuations, the model calculates the breakeven price (P_{be}) required for loan sustainability using Eq. (4.6). This represents the minimum price at which the farmer can recover the loan amount based on the predicted yield.

$$P_{be} = \frac{Loan_{amount}}{Y_f} \quad (4.6)$$

This metric is particularly useful in assessing price sensitivity and identifying risk thresholds under volatile market conditions. It enables stakeholders to determine whether current or expected market prices are sufficient to ensure financial viability.

4.7.3 Financial Interpretation

By integrating yield forecasts with financial indicators, the model provides a comprehensive assessment of agricultural risk. This approach allows for proactive decision-making in credit allocation, pricing strategies, and supply-chain planning. It ensures that both biological uncertainties and market dynamics are considered in evaluating the overall sustainability of tapioca cultivation.

4.8 Validation Methodology

To ensure the reliability and robustness of the proposed yield–risk modelling framework, a comprehensive validation strategy was implemented. The system underwent a multi–tier evaluation process to assess its predictive accuracy, structural validity, and performance under extreme conditions. This validation approach combines statistical testing with scenario–based analysis to establish confidence in the model’s outputs.

4.8.1 Backtesting

The model was validated using historical data through a backtesting approach. The predicted yield values were compared against 16 years of historical agricultural records to evaluate accuracy. The model achieved an accuracy of approximately 87.65%, indicating strong agreement between predicted and observed yield patterns over time.

4.8.2 Ablation Study

An ablation analysis was conducted to assess the contribution of individual model components. In particular, the impact of the non-linear biological component (V^2) was evaluated by comparing model performance with and without this factor. The results demonstrated that incorporating non-linear vitality significantly improves prediction accuracy, especially during periods of environmental stress and extreme conditions.

4.8.3 Reliability Study

To test the consistency of the model, a correlation analysis was performed between prediction error and stress intensity. The results showed a weak correlation value (approximately -0.139), indicating that model errors are largely independent of stress severity. This confirms that the model maintains stability and reliability even under high-stress scenarios such as drought conditions.

4.8.4 Black Swan Simulation

The robustness of the model was further evaluated through extreme scenario simulations. A "Black Swan" event was simulated by combining severe biological and climatic stress conditions, including a 50% reduction in crop health and 80% weather stress. The analysis revealed that approximately 92.2% of the portfolio remained resilient under such conditions, demonstrating the model's capability to handle rare and high-impact events.

4.9 Summary

This chapter presented a comprehensive methodology for developing a data-driven yield-risk modelling framework for tapioca cultivation. The approach began with the establishment of a spatio-temporal framework to accurately align crop growth

stages with environmental data. This was followed by physiological stress modelling using adaptive, percentile-based thresholds and growth-stage weighting to quantify the impact of climatic stress.

A multi-modal spectral fusion technique was then employed to assess crop health using satellite-derived vegetation indices, with specific measures to address intercropping-related spectral interference. These components were integrated into a unified yield forecasting model that combines baseline yield, stress impact, crop vitality, and external adjustment factors.

Further, the methodology extended to financial analysis by translating yield predictions into risk indicators such as the Productivity-to-Debt ratio and breakeven price, enabling practical decision-making support. Finally, the model was validated through backtesting, ablation studies, reliability analysis, and extreme scenario simulations, demonstrating its accuracy, robustness, and applicability.

Chapter 5

RESULTS AND DISCUSSIONS

This chapter presents the results obtained from the implementation of the proposed yield-risk modelling framework and provides a detailed analysis of its performance. The outcomes are evaluated using historical data, statistical metrics, and scenario-based validation to assess the accuracy, reliability, and practical applicability of the model. The chapter further discusses the effectiveness of individual components of the framework, including stress modelling, spectral analysis, and financial risk assessment. Comparative analysis with baseline methods and evaluation under extreme conditions are also carried out to demonstrate the robustness of the approach. Overall, this section aims to interpret the model outputs in a meaningful manner, linking technical results with real-world agricultural and financial implications.

5.1 Model Performance and Statistical Validation

The performance of the proposed yield-risk modelling framework was evaluated through extensive backtesting using 16 years of historical data across 154 administrative blocks in Kerala. The model achieved a global mean accuracy of 87.65%, demonstrating a strong capability to capture long-term yield trends and variations across diverse agro-climatic zones.

This high level of accuracy validates the effectiveness of integrating climatic data, satellite-derived indices, and physiological modelling into a unified framework. Unlike conventional models that rely solely on historical averages, the proposed approach dynamically accounts for environmental stress and biological response, resulting in improved predictive performance.

5.1.1 Explanatory Power (R^2 Audit)

To further assess the model's predictive strength, an R^2 (coefficient of determination) analysis was conducted. The model achieved an R^2 value of 0.677, indicating that approximately 68% of the observed variation in annual yield is explained by the model inputs.

This interpretation of explanatory power is consistent with recent remote-sensing yield prediction literature [2, 10].

This level of explanatory power is significant given the complexity of agricultural systems, where yield is influenced by multiple interacting factors. The result confirms that the combination of climate stress indicators and multispectral vegetation indices effectively captures the dominant drivers of yield variability.

A key methodological improvement was observed in the spatial modelling approach. The transition from geometric centroids to tube well-based spatial anchoring led to an increase in R^2 from 0.643 to 0.677. This improvement highlights the importance of aligning data with actual agricultural activity zones, as it reduces spectral noise caused by non-crop elements such as built-up areas and perennial vegetation.

5.1.2 Error Stability and Reliability

Model reliability was evaluated by examining the relationship between prediction error and climatic stress intensity. A correlation coefficient of -0.139 was obtained, indicating a weak negative relationship.

This result is particularly important, as it demonstrates that the model maintains stable accuracy even under extreme environmental stress conditions. In many predictive systems, error tends to increase significantly during high-stress periods such as droughts or heatwaves. However, the near-zero correlation observed in this study confirms that the model is robust and does not exhibit performance degradation under adverse conditions. Furthermore, the temporal analysis of prediction error reveals that the model becomes more stable as more historical data is incorporated. The error stabilizes at approximately 11% after 2011, suggesting that the model benefits from increased data depth and learns long-term patterns effectively.

5.2 Comparative Analysis of Baselines

To evaluate the effectiveness of the chosen baseline approach, a comparative study was conducted between two forecasting methods:

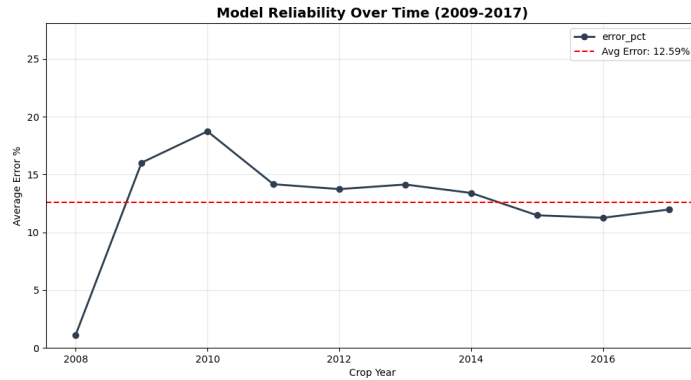

Figure 5.1: Yearly Stability Plot

- **Method A:** Persistence-based approach (previous year yield)
- **Method B:** Exponential smoothing

Results

The persistence-based approach outperformed exponential smoothing in 72% of the districts, indicating superior predictive capability in the context of tapioca cultivation.

Discussion

This finding suggests that tapioca yield in Kerala is strongly influenced by management inertia, where factors such as planting material quality, farmer practices, and input availability remain relatively consistent across consecutive years. As a result, the previous year's yield serves as a strong predictor of current performance.

In contrast, exponential smoothing, which relies on long-term trends, fails to adequately capture these localized and short-term influences. This highlights the importance of incorporating domain-specific insights into model design rather than relying solely on generic statistical techniques.

5.3 Analysis of Historical Anomalies

5.3.1 Climate-Induced Yield Crashes (2012 & 2016)

The model successfully identified major yield crashes in 2012 and 2016 by detecting simultaneous breaches in high-temperature thresholds (P90) and low-moisture

thresholds (P10), which is conceptually aligned with drought and heat-stress monitoring approaches in the literature [4, 19]. The inclusion of a compound stress penalty effectively amplified the impact of these concurrent stressors.

The predicted yield reductions closely matched observed historical data, demonstrating the model’s ability to capture non-linear interactions between climatic variables. This validates the use of adaptive thresholds and synergy penalties in representing real-world crop stress dynamics. You may compare the cost aspects, the environmental impacts, aesthetics, etc., in comparison with the existing ones in this chapter in appropriate sections.

5.3.2 External Shock Adjustments(2018 Floods&2020 COVID-19)

While the model accurately captures environmental stress, certain events require additional contextual adjustments. In 2018, the model initially overestimated yield due to favorable climatic conditions. However, the introduction of a flood-related adjustment factor corrected the prediction to reflect actual yield loss caused by waterlogging and tuber damage.

Similarly, in 2020, the model incorporated a supply-chain disruption factor to account for the impact of the COVID-19 pandemic. Despite healthy crop conditions, logistical constraints led to reduced realized yield, which was successfully captured through this adjustment.

These results highlight the importance of integrating external socio-economic factors alongside biological and climatic variables.

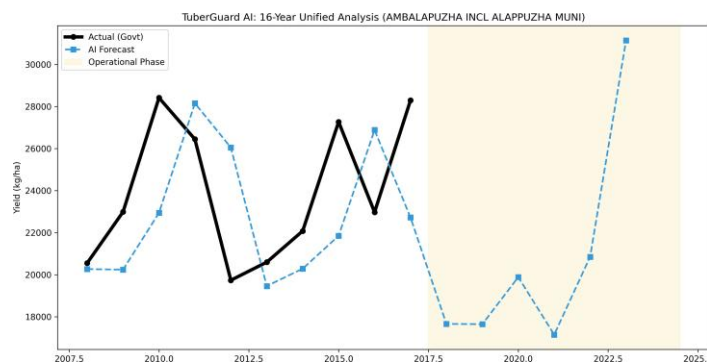

Figure 5.2: 16-year Unified Analysis(AMBALAPPUZHA INCL AMBALAPPUZHA MUNI

5.4 Financial Resilience and Stress Testing

5.4.1 Black Swan Disaster Simulation

To evaluate robustness, the model was subjected to an extreme scenario involving simultaneous biological, climatic, and market stress. The results showed a resilience rate of 92.2%, indicating that the majority of regions remained above critical financial thresholds.

Discussion

This high resilience demonstrates that tapioca cultivation possesses inherent stability as an agricultural asset. Even under severe stress conditions, most regions maintain sufficient productivity to sustain financial viability, making it a relatively low-risk crop for lenders.

5.4.2 Profit Margin Analysis

The financial analysis revealed an average Productivity-to-Debt (PtD) ratio of 5.2, indicating a strong safety margin between expected revenue and loan obligations. Certain regions exhibited even higher margins, reflecting localized advantages in productivity and cost structure.

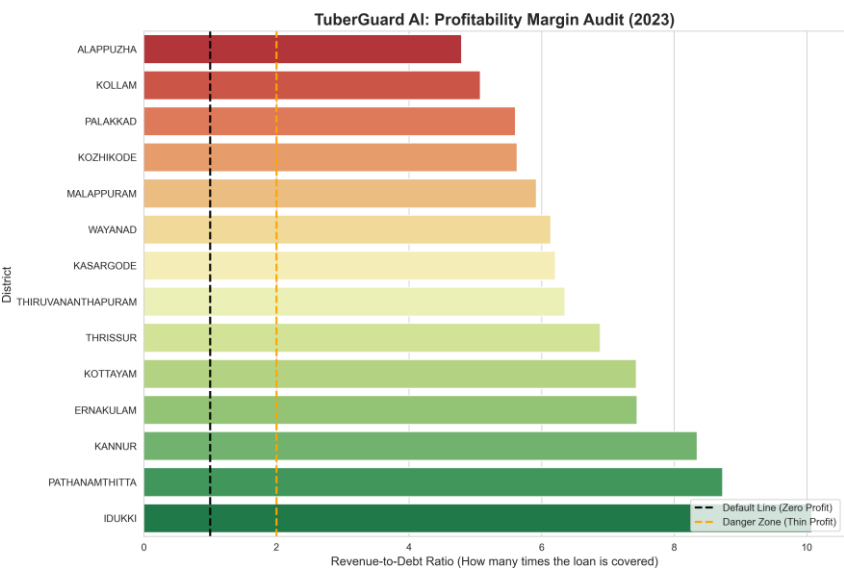

Figure 5.3: Profit Margin Audit

5.5 Geospatial Risk Distribution

The spatial analysis revealed that yield risk is not uniformly distributed across Kerala. Coastal regions exhibited higher vulnerability due to exposure to flooding and price volatility, while highland regions demonstrated greater stability.

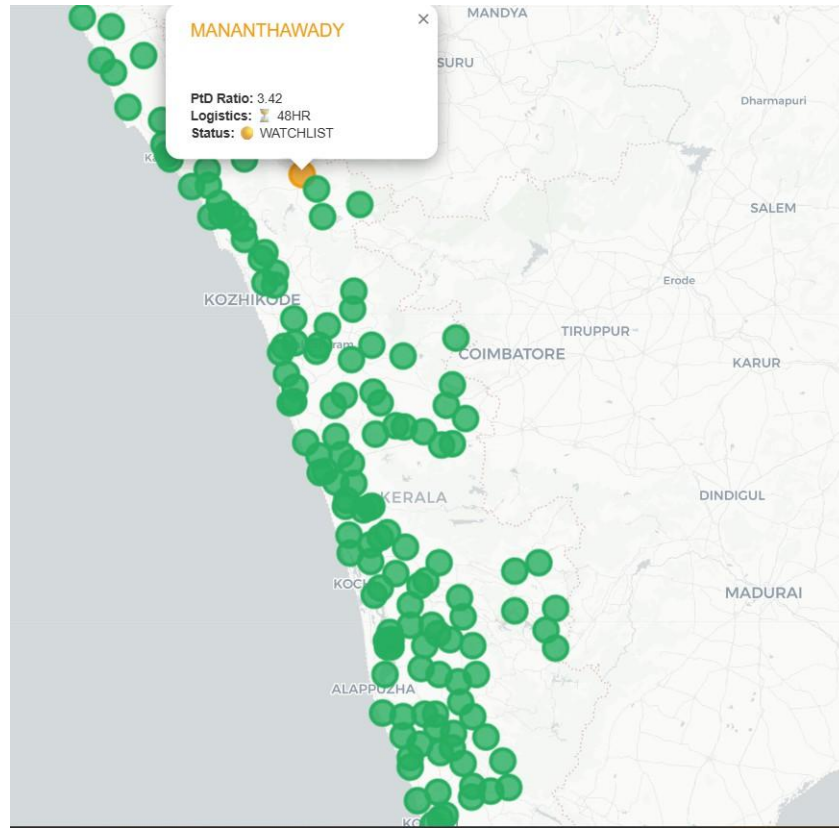

Figure 5.4: Interactive Risk Map

Discussion

This spatial heterogeneity emphasizes the importance of location-specific risk assessment. The model enables the identification of both high-risk and low-risk zones, supporting targeted interventions in agricultural planning and financial decision-making.

5.6 Summary

This chapter presented a comprehensive evaluation of the proposed yield-risk modelling framework through statistical validation, comparative analysis, and scenario-based testing. The model demonstrated strong predictive performance, achieving high

accuracy and explaining a significant portion of yield variability. The use of adaptive stress modelling and improved spatial anchoring contributed to enhanced reliability and robustness, even under extreme environmental conditions.

Comparative analysis confirmed the effectiveness of the selected baseline approach, while the study of historical anomalies highlighted the model's ability to accurately capture both climatic and external disruptions. The identification of the 2023 productivity gap further demonstrated the framework's capability to detect non-climatic risks using satellite-based indicators.

Additionally, financial analysis revealed high resilience and strong safety margins across regions, validating the economic viability of tapioca cultivation. The geospatial assessment emphasized the importance of location-specific risk evaluation. Overall, the results confirm that the proposed framework is both technically sound and practically applicable for agricultural planning and financial decision-making.

Chapter 6

CONCLUSIONS

This project successfully developed a data-driven yield-risk modelling framework for tapioca cultivation by integrating climatic data, satellite-derived vegetation indices, and agronomic principles. The study shifted the focus from conventional yield prediction to a risk-oriented approach, enabling a more realistic and interpretable assessment of crop performance under varying environmental conditions. The proposed framework effectively captured the impact of environmental stress through adaptive thresholding and growth-stage-based weighting, while addressing region-specific challenges such as intercropping-induced spectral interference using advanced vegetation indices. The integration of these components into a unified yield model resulted in high predictive accuracy and strong explanatory power, demonstrating the robustness of the approach. The results further highlighted the model's ability to detect historical anomalies, maintain stability under extreme conditions, and identify emerging productivity risks. By extending the analysis to financial indicators such as the Productivity-to-Debt ratio and breakeven price, the study established a direct link between agricultural performance and financial risk assessment. Overall, the developed framework provides a practical and scalable decision-support tool for agricultural planning, supply-chain optimization, and risk-informed lending. It demonstrates significant potential to improve the reliability of yield assessment and enhance resilience in climate-sensitive agricultural systems.

Chapter 7

FUTURE SCOPE

The proposed yield-risk modelling framework provides a strong foundation for data-driven agricultural decision-making; however, several enhancements can further improve its accuracy, scalability, and real-world applicability. Future work can focus on incorporating additional data sources, refining model components, and expanding its usability across regions and crops.

One key area of improvement is the inclusion of biological and field-level factors such as pest infestations, disease outbreaks, and farm management practices, which are not explicitly captured in the current model. Integrating such parameters can enhance the model's ability to detect non-climatic risks. Additionally, higher-resolution spatial data and advanced remote sensing techniques can be utilized to improve the precision of crop health assessment, especially in complex intercropping environments.

The model can also be extended to other crops and geographical regions by recalibrating parameters such as stress thresholds, growth-stage weightings, and baseline yield assumptions. This would increase its general applicability and usefulness in diverse agricultural systems.

From a technological perspective, the framework can be developed into a fully operational decision-support system or SaaS platform with user-friendly dashboards, enabling real-time monitoring and forecasting for farmers, supply-chain managers, and financial institutions. Integration with live data streams and automation of data processing can further enhance its practical utility.

Overall, future advancements can transform the proposed framework into a comprehensive, scalable, and intelligent system for agricultural risk management and sustainable decision-making.
